Metric-dependent magnitude of spatial leakage

a leave-one-county-out evaluation of the Bijie landslide benchmark

nine YOLO26n models | eight county folds | 770 landslide instances | 2003 negative patches

Same trained model, same test images, same county → the measured gap varies by nearly an order of magnitude

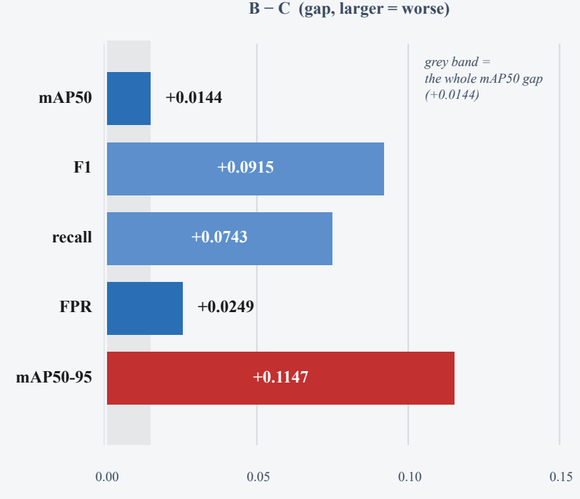

A — Eight county-level folds (Bijie)

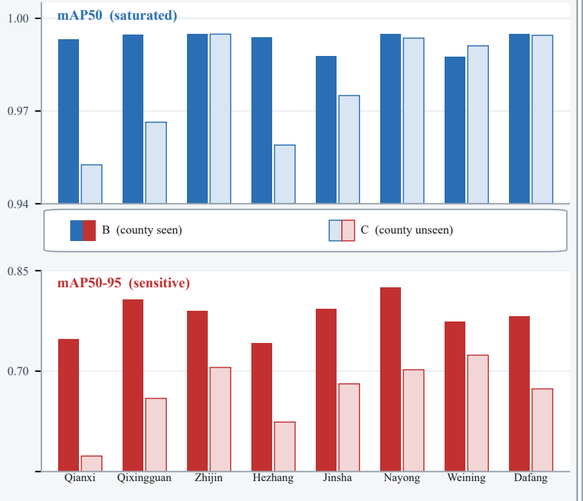

Each fold: hold out one county → train on the other seven

dots ≈ test patches (770 instances in total)

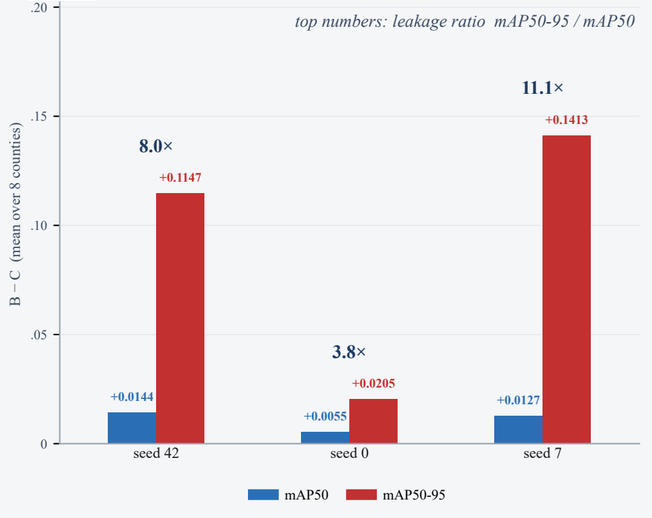

B — One model, five metrics → five different gaps

C — mAP50 saturated vs. mAP50-95 sensitive

D — Robust across three random seeds

mAP50 looks safe (+0.0144) → mAP50-95 reveals 3.8× – 11.1× larger leakage

Take-home: the metric, not the split alone, decides what the paper reports.
